The Isotropy Group of a Topos

(cf. Funk - Hofstra - Steinberg 2012)

Let \mathcal{I} be a topos & consider the functor

$$\mathcal{Z}: \mathcal{I}^{\text{op}} \longrightarrow \text{Grp}$$

$$\mathcal{Z}(X) = \text{Aut}(X^*: \mathcal{I} \rightarrow \mathcal{I}/X).$$

So $\mathcal{Z}(X)$ consists of natural automorphisms of the pullback functor:

$$\begin{array}{ccc} \mathcal{I} & \xrightarrow{\quad F \quad} & \mathcal{I} \times X \\ & & \downarrow \pi_2 \\ & & X \end{array} \in \mathcal{I}/X$$

A map $X \xleftarrow{f} Y$ acts by whiskering with pullback:

$$\mathcal{I} \xrightarrow{\exists} \mathcal{I}/X \xrightarrow{f^*} \mathcal{I}/Y$$

$$\mathcal{Z}(X) \ni \alpha \longrightarrow f^* \cdot \alpha \in \mathcal{Z}(Y)$$

Briefly:

$$\alpha \in \mathcal{Z}(X) = \text{Aut}(X^*)$$

$$X^*: \mathcal{I} \xrightarrow{\exists} \mathcal{I}/X$$

(2)

Prop. The functor $\mathcal{Z} : \mathcal{F}^{\text{op}} \rightarrow \text{Grp}$ is representable,

$$\mathcal{Z} \cong \mathcal{Z}(-, Z) ,$$

for a group object Z in \mathcal{L} ,
called the isotropy group of \mathcal{Z} .

Remark The group $Z_{\mathcal{E}}$ also acts on
 the \mathcal{E} -valued points $p : \mathcal{E} \rightarrow \mathcal{Z}$,
 for any types \mathcal{E} , in the following sense:
 For any global $\alpha : 1 \rightarrow Z$ we have
 a natural automorphism:

$$1 : \mathcal{Z} \xrightarrow{\quad \sim \quad} \mathcal{Z}/_1 \cong \mathcal{Z} .$$

So for each $F \in \mathcal{L}$ we have an iso

$$\begin{array}{ccc} F & \xrightarrow[\sim]{\alpha_F} & F \\ \downarrow & & \downarrow \\ E & \xrightarrow[\sim]{\alpha_E} & E \end{array} \quad \text{natural in } F !$$

(3)

And moreover, for all $X \in \mathcal{L}$,

$$\begin{array}{ccc} \mathcal{L} & \xrightarrow{\alpha_X^{-1}} & \mathcal{L} \\ \downarrow f & & \downarrow f^* \\ \mathcal{L}/X & \xrightarrow{\alpha_X} & X^* \end{array} \quad \text{and} \quad \alpha_X = X^* \cdot \alpha_1$$

since α is natural in X .

Conversely, given any natural automorphism

$$f_\alpha: \mathcal{L} \xrightarrow{\alpha} \mathcal{L}$$

Whiskering by any $P: \mathcal{E} \rightarrow \mathcal{L}$

results in

$$\mathcal{E} \xrightarrow{\alpha \circ P} \mathcal{L}$$

Prop. There's a group isomorphism:

$$\Gamma \mathcal{L}_g \xrightarrow{\sim} \text{Aut}(f_\alpha)$$

between global sections of \mathcal{L}_g and the center of \mathcal{L} : the group of natural

automorphisms of the identity $f_\alpha: \mathcal{L} \rightarrow \mathcal{L}$.

(4)

Now suppose that $\mathcal{L} = \text{Set}[\mathbb{T}]$ classifies \mathbb{T} -models. Then for any topos \mathcal{E} we get an action of

(sections of) the group $Z_{\mathbb{T}}$ of $\text{Set}[\mathbb{T}]$ on \mathbb{T} -models in \mathcal{E} , since

$$\text{Mod}_{\mathbb{T}}(\mathcal{E}) \cong \text{Top}(\mathcal{E}, \text{Set}[\mathbb{T}]) ,$$

and we just saw that $T^*Z_{\mathbb{T}}$ acts naturally on the RHS.

This leads to the following idea:

Prop. (A-B 2012) Let $S[\mathbb{T}]$ be

a classifying topos for a theory \mathbb{T} , with universal \mathbb{T} -model $U_{\mathbb{T}}$. Then the isotropy group $Z_{S[\mathbb{T}]}$ agrees with the internal automorphism group of the \mathbb{T} -model $U_{\mathbb{T}}$,

$$Z_{S[\mathbb{T}]} \cong \text{Aut}(U_{\mathbb{T}}) .$$

Internal vs. External

(5)

- The external group of sections

$\mathrm{T}^1\mathbb{Z}_{\mathbb{F}}$ in Set

acts naturally on all \mathbb{F} -models
(in all toposes) :

$$\alpha \in \mathrm{T}^1\mathbb{Z}_{\mathbb{F}} \quad \begin{array}{ccc} M & \xrightarrow[\sim]{\alpha_M} & N \\ h \downarrow & & \downarrow h \\ T & \xrightarrow[\sim]{\alpha_T} & N \\ & & \alpha_N \end{array}$$

- The internal group object

$\mathbb{Z}_{\mathbb{F}}$ in $\mathrm{S}[\mathbb{F}]$

does something more :

For any model M (in any \mathcal{E}),
there's a stalk. $(\mathbb{Z}_{\mathbb{F}})_M$ s.t.

- for $\alpha \in \mathrm{T}^1(\mathbb{Z}_{\mathbb{F}})_M$ there's $M \xrightarrow[\sim]{\alpha_M} N$

- and for any $h: M \rightarrow N$ there's $\alpha_h: N \rightarrow N$ s.t. $N \xrightarrow[\sim]{\alpha_h} N$.

Logical Schemes

(6)

Let \mathbb{T} be a coherent theory, and

$\mathcal{E}_{\mathbb{T}}$ the classifying pretopos, so the classifying topos is :

$$S[\mathbb{T}] = Sh(\mathcal{E}_{\mathbb{T}})$$

In $S[\mathbb{T}]$ there is a pretopos $\tilde{\mathcal{E}}_{\mathbb{T}}$, given by strictifying the stack:

$$\tilde{\mathcal{E}}_{\mathbb{T}} : \mathcal{E}_{\mathbb{T}}^{\text{op}} \longrightarrow \text{Cat}$$

$$\tilde{\mathcal{E}}_{\mathbb{T}}(X) = \mathcal{E}_{\mathbb{T}}/X,$$

corresponding to the codomain fibration

$$\begin{array}{ccc}
 & \xrightarrow{\quad} & \\
 \mathcal{E}_{\mathbb{T}} & \downarrow \text{Cod} & \\
 & \downarrow & \\
 \mathcal{E}_{\mathbb{T}} & &
 \end{array}$$

Prop. $\tilde{\mathcal{E}}_{\mathbb{T}}$ is a sheaf representation

of $\mathcal{E}_{\mathbb{T}}$, in the sense $T\tilde{\mathcal{E}}_{\mathbb{T}} \cong \mathcal{E}_{\mathbb{T}}$.

Groupoid of Models (7)

We then make $\mathcal{E}_{\mathbb{F}}$ into an equivariant sheaf on the groupoid of \mathbb{T} -models :

$$G_{\mathbb{F}} = G_{\mathbb{F}} \xrightarrow{\sim} X_{\mathbb{F}} .$$

Where:

$X_{\mathbb{F}}$ = Space of \mathbb{T} -models

$G_{\mathbb{F}}$ = Space of \mathbb{T} -modelisos .

The groupoid $G_{\mathbb{F}}$ supports the
groupoid representation of $S[\mathbb{F}]$:

$$S[\mathbb{F}] \simeq Sh(G_{\mathbb{F}})$$

$$\simeq Sh_{\text{eq}}(G_{\mathbb{F}}) ,$$

where $Sh_{\text{eq}}(G_{\mathbb{F}})$ is the topos of
 $G_{\mathbb{F}}$ equivariant sheaves on $X_{\mathbb{F}}$.

See: Joyal-Tierney, Butz-Moeudijk,
A.-Forssell, Breiner .

Now move the sheaf $\tilde{\mathcal{E}}_{\mathbb{T}}$ across
the equivalence

$$\mathrm{Sh}(\mathcal{E}_{\mathbb{T}}) \cong \mathrm{Sh}_{\mathbb{G}}(\mathbb{G}_{\mathbb{T}})$$

to get an equivalent sheaf on $\mathbb{G}_{\mathbb{T}}$,
called the structure sheaf of the
logical scheme

$$(\mathbb{G}_{\mathbb{T}}, \tilde{\mathcal{E}}_{\mathbb{T}})$$

of the theory \mathbb{T} . (Brincker 2012)

Remark. There's also the constant
equivariant sheaf $\Delta \tilde{\mathcal{E}}_{\mathbb{T}}$ on $\mathbb{G}_{\mathbb{T}}$,
and a canonical map

$$\eta: \Delta \tilde{\mathcal{E}}_{\mathbb{T}} \rightarrow \tilde{\mathcal{E}}_{\mathbb{T}},$$

namely the transpose of the equivalence

$$\mathcal{E}_{\mathbb{T}} \xrightarrow{\sim} \mathrm{T}^* \tilde{\mathcal{E}}_{\mathbb{T}}.$$

Prop. The isotropy group $I_{\mathbb{F}}$

of \mathbb{F} is isomorphic to the group of automorphisms of η :

$$I_{\mathbb{F}} \cong \text{Aut}(\Lambda^{\wedge}_{\mathbb{F}} \xrightarrow{\sim} \tilde{\mathcal{E}}_{\mathbb{F}}).$$

Corollary. The stalk of $I_{\mathbb{F}}$ at

a model M is the group of inner automorphisms: "definable"

automorphisms w/ parameters from M

$$(I_{\mathbb{F}})_M \cong \text{Aut}_i(M).$$

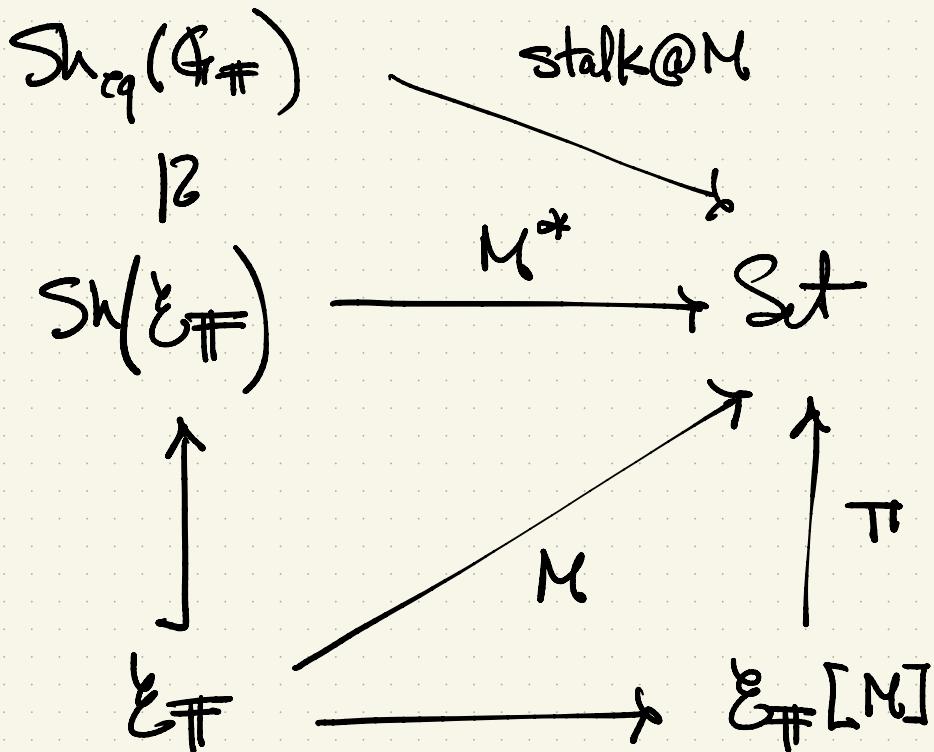

Pf:

$$(I_{\mathbb{F}})_M \cong \text{Aut}(\Lambda^{\wedge}_{\mathbb{F}} \xrightarrow{\sim} \tilde{\mathcal{E}}_{\mathbb{F}})_M$$

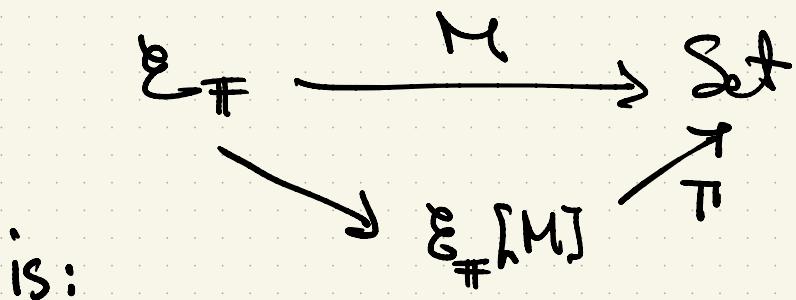

$$\cong \text{Aut}(M^{\wedge} \Lambda^{\wedge}_{\mathbb{F}} \xrightarrow{\sim} M^{\wedge} \tilde{\mathcal{E}}_{\mathbb{F}})$$

$$\cong \text{Aut}(\mathcal{E}_{\mathbb{F}} \xrightarrow{\sim} \mathcal{E}_{\mathbb{F}[M]}). \dots$$

(10)

where $\mathcal{E}_{\#}[M]$ in the factorization

$$\begin{aligned}
 \mathcal{E}_{\#}[M] &= (\tilde{\mathcal{E}}_{\#})_M \simeq M^*(\tilde{\mathcal{E}}_{\#}) \\
 &= \varinjlim_{SM} \mathcal{E}_{\#}/(-) = \mathcal{E}_{\#|M}.
 \end{aligned}$$

Thus $\mathcal{E}_{\#|M}$ is the theory of M.

(11)

The stalk of the isotropy group
at M is then :

$$\begin{aligned} (\mathcal{I}_{\#})_M &\simeq \text{Aut}_i(M) \\ &\simeq \text{Aut}(\mathcal{E}_{\mathbb{F}} \rightarrow \mathcal{E}_{\mathbb{F}[M]}) \\ &\simeq \text{Aut}(\mathcal{U}_{\mathbb{F}[M]}), \end{aligned}$$

which is internal to the syntactic
pretopos $\mathcal{E}_{\mathbb{F}[M]}$ and therefore
in the syntax of $\mathbb{F}[M]$.

Remark. The stalk pretopos $\mathcal{E}_{\mathbb{F}[M]}$
is local, in the sense that its
 $T^i : \mathcal{E}_{\mathbb{F}[M]} \rightarrow \text{Set}$ is a
pretopos functor : I is projective
& indecomposable.
